

# PCMI 2021: Supersingular isogeny graphs in cryptography

## Exercises Lecture 3: Quaternion algebras, Endomorphism rings

TA: Jana Sotáková

version July 30, 2021

All the commands are in Magma. Similar commands also exist for Sage.

Solutions for the first 3 exercises are on the [website](#) if you want to focus on Exercise 4.

- (Quaternion algebras and orders) For small primes  $p$ , define the quaternion algebra  $B := B_{p,\infty} = \mathbb{Q}\langle 1, i, j, k \rangle$  with  $i^2 = -r$  and  $j^2 = -p$  and  $ij = -ji = k$ :
  - Use `QuaternionAlgebra< RationalField() | -r, -p >`;
  - For  $p \equiv 3 \pmod{4}$ , use  $-r = -1$ ;
  - For  $p \equiv 5 \pmod{8}$ , use  $-r = -2$ ;
  - Otherwise, find  $r$  as a prime  $r \equiv 3 \pmod{4}$  such that  $\left(\frac{r}{p}\right) = -1$ .

Verify that  $B$  is only ramified at  $p$  and infinity (`RamifiedPrimes`). Find the discriminant of  $B$ . Note that again, ramified primes are those that divide the discriminant. In the last exercise 5, you will see what makes the ramified primes special.

Verify that  $i^2 = -r$  and  $j^2 = -p$ . Find the norm, trace and the minimal polynomial of the element  $w = 2 + i - 3j + 4k$ .

- (Maximal orders) Write down a maximal order in each of the quaternion algebras. You can find examples for different congruence conditions on  $p$  in Lemmas 2-4 in [Kohel-Lauter-Petit-Tignol](#).
  - Using the Magma command `MaximalOrder`;
  - Using a basis and `QuaternionOrder`;

Find the discriminant and the norm form of the maximal order. `GramMatrix`

- For  $p = 67$ , take any maximal order  $\mathcal{O} \subset B_{p,\infty}$ . Then:
  - Enumerate all the left-ideal classes in  $\mathcal{O}$ ; `LeftIdealClasses`
  - For every ideal class, pick a representative and find the right order of the ideal; `RightOrder`;
  - Check how many isomorphism classes there are as right orders. Deduce the number of supersingular  $j$ -invariants in  $\mathbb{F}_p$  and pairs of conjugate  $j$ -invariants in  $\mathbb{F}_p^2$ . Hint available.
  - Compute the norm of all these ideals;
  - Figure out which of these maximal orders correspond to elliptic curves defined over  $\mathbb{F}_p$ . Show that the following suffices:
    - Compute the norm form of these maximal orders; Hint available.
    - Find out whether they represent  $p$ ;

Check the count by looking at how many supersingular  $j$ -invariants there are in  $\mathbb{F}_p$ .

- ("Effective Deuring Correspondence") In this exercise, you will be matching endomorphism rings to supersingular elliptic curves. For  $p = 67$ , determine the endomorphism rings of all supersingular elliptic curves defined over  $\mathbb{F}_{p^2}$ :

- (a) List all the maximal orders in  $B_{p,\infty}$ ;
- (b) Find the connecting ideals for some of these orders;

Note that you can build them as follows: for maximal orders  $\mathcal{O}_1, \mathcal{O}_2$ :

- Let  $N = [\mathcal{O}_1 : \mathcal{O}_1 \cap \mathcal{O}_2]$ . Compute intersections using `O1 meet O2`;
- Then take  $I := N\mathcal{O}_1 + N\mathcal{O}_1\mathcal{O}_2$ .  
You can define such ideals using `LeftIdeal(Order ,Generators)` where `Generators` is any tuple.
- Verify that this ideal is integral.
- Verify that it is a left  $\mathcal{O}_1$ -ideal and right  $\mathcal{O}_2$ -ideal;
- Compute its norm.

- (c) List all the supersingular  $j$ -invariants;
- (d) Start from an elliptic curve with ‘known’ endomorphism ring, e.g.  $E : y^2 = x^3 - x$ ;
- (e) For small  $\ell$ , compare the  $\ell$ -isogenies between the elliptic curves and ideals of norm  $\ell$ . Use (3e) to narrow down the orders for elliptic curves defined over  $\mathbb{F}_p$ .

You can find more things that will help you distinguish the orders and match them to elliptic curves in [Cervino](#) and [Lauter and McMurdy](#) and in the [WIN-4 collaboration](#).

- 5. (Quaternion algebras and Matrix rings) coming soon!

## Hints, comments, commands

3. c) Deuring's correspondence can be written in two ways:

- $j$ -invariants (up to conjugation in  $\mathbb{F}_{p^2}$ , that is,  $j \mapsto j^p$ ) correspond to maximal orders up to isomorphism of maximal orders (that is, conjugation in the quaternion algebra  $B$  - Skolem Noether);
- Starting from an elliptic curve  $E$ , the left ideal classes in  $\mathcal{O} := \text{End}(E)$  correspond to supersingular elliptic curves, such that if  $E1 \leftrightarrow \mathcal{O}_1$  then the right order can be identified with  $O_R(I) = \text{End}(\mathcal{O}_1)$ .

For  $j$ -invariants in  $\mathbb{F}_p^2$ , the endomorphism rings of supersingular elliptic curves with  $j$ -invariants  $j$  and  $j^p$  are isomorphic as orders in the quaternion algebra, even though the curves are not isomorphic. So if you find 6 left ideal classes and 4 non-isomorphic maximal orders, you see that exactly 2 supersingular  $j$ -invariants are in  $\mathbb{F}_p$ .

3. e) Curves over  $\mathbb{F}_p$  have the Frobenius endomorphism in their endomorphism ring, which is an endomorphism of norm  $p$  and trace 0.

You can use the `GramMatrix`, which is the Gram matrix for the inner product  $\langle x, y \rangle$  on the maximal order satisfying  $\text{Norm}(x) = 1/2 \langle x, x \rangle$ .

You can create a quadratic form from the Gram matrix: `QuadraticForm(GramMatrix(O));`.

So you need to represent the element  $2p$  in this quadratic form. Note that  $\text{Tr}(x) = 0$  means that the first coordinate can be set to 0 (if the order has 1 in its basis). But Magma doesn't naturally create orders with 1 in the basis, so you can't just set  $a = 0$ .
